

Applied Computer Architecture

*Virus*

05/22/2024

I have never experienced a problem with any malware therefore, I will talk about the famous MyDoom virus. This virus works by spreading from one computer to another via email attachments. It appears as a message, and when you open the attachments, the program will sit on your computer. Not only your computer is affected by it, but also everyone in your address book. In January and February of 2004, many people received mysterious emails saying, "I'm just doing my job, nothing personal, sorry." These emails came with an attachment, and each time people checked their inboxes, their contact would get another copy. When MyDoom affects your computer, it turns it into a zombie because it has a certain control over your email recipients. Until now, the developer of this code is still unknown, but there is some speculation that MyDoom has similarities with codes developed in some Russian labs.

Windows users were the only ones affected by MyDoom. They didn't know the issue but experienced slow speeds or glitchy service. MyDoom is a dangerous virus because of how fast it spreads compared to any other virus. SCO Group and Microsoft were two major companies affected when it first appeared. SCO Group was bombarded with homepage requests, which caused the site to crash. It took the company one hour to change its website addresses altogether. Infected computers bombarded Microsoft's website, and computers couldn't access antivirus websites to fix this. People were only able to clean up their computers.

Any computer infected with MyDoom has a risk of being hijacked by attackers, which is why it is important to take these signs seriously: more time to open, close, and save Windows files; people saying they received mysterious emails from you; and an increased need for bandwidth even on a managed network.
